Attention!

- -It is not allowed to use the unit if the covers have been removed.
- -We decline all responsibility for damages and injuries caused by an improper use of the module. It is highly recommended to read the operators manual before any kind of operation.

Note

The information in this manual is subject to change without notice. We take no responsibility whatsoever for any error in the document. We reserve the right to make changes in the product design without reservation and without notification to the users.

Filename VHQx0x.____; version 3.00 as of 20.06.2003

1. General information

The VHQ's are one or two channel high voltage supplies in 6U VME format, 164 mm deep, double width. The units offers manual control and operation via VME bus. The use of the VME interface supports more then the manual control functionality.

The high voltage supplies special provide high precision output voltage together with very low ripple and noise, even under full load. Separate 10%-steps hardware switches put voltage and current limits. An INHIBIT input protects connected sensitive devices. Additionally, the maximal output current per channel is programmable via the interface. The high voltage outputs protected against overload and short circuit. The output polarity can be switched over.

2. Technical data:

VHQ one cha	innel	102M	103M	104L	105L

3. VHQ Description

The function is described at a block diagram of the VHQ. This can be found in Appendix A.

High voltage supply

A patented high efficiency resonance converter circuit, which provides a low harmonic sine voltage on the HV-transformer, is used to generate the high voltage. The high voltage is rectified using a high speed HV-rectifier, and the polarity is selected via a high-voltage switch. A consecutive active HV-filter damps the residual ripple and ensures low ripple and noise values as well as the stability of the output voltage. A precision voltage divider is integrated into the HV-filter to provide the set value of the output voltage, an additional voltage divider supplies the measuring signal for the maximum voltage control. A precision measuring and AGC amplifier compares the actual output voltage with the set value given by the DAC (computer control) or the potentiometer (manual control). Signals for the control of the resonance converter and the stabilizer circuit are derived from the result of the comparison. The two-stage layout of the control circuit results in an output voltage, stabilized with very high precision to the set point.

Separate security circuits prevent exceeding the front-panel switch settings for the current I_{max} and voltage V_{max} limits. A monitoring circuit prevents malfunction caused by low supply voltage.

The internal error detection logic evaluates the corresponding error signals and the external INHIBIT signal. It allows the detection of short overcurrent due to single flashovers in addition.

Digital control unit

A micro controller handles the internal control, evaluation and calibration functions of both channels. The actual voltages and currents are read cyclically by an ADC with connected multiplexer and processed for display on the 4 digit LCD display. The current and voltage hardware limits are retrieved cyclically several times per second. The reference voltage source provides a precise voltage reference for the ADC and generation of the control signals in the manual operation mode of the unit.

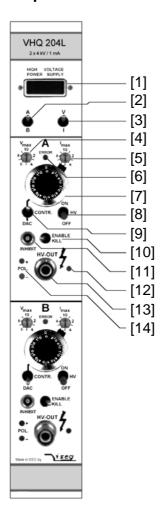

The set values for the corresponding channels are generated by a 16-Bit DAC in computer controlled mode.

<u>Filter</u>

A special property of the unit is a tuned filtering concept, which prevents radiation of electromagnetic interference into the unit, as well as the emittance of interference by the module. A filtering network is located next to the connectors for the supply voltage and the converter circuits of the individual devices are also protected by filters. The high-voltage filters are housed in individual metal enclosures to shield even minimum interference radiation.

5. Handling

The state of readiness of the unit is produced at the VME connector on the flipside.

The Output polarity is selectable with help of a rotary switch on the cover side (see appendix B). The chosen polarity is displayed by a LED on the front panel [14] and a sign on the LCD display [1].

Attention! It is not allowed to change the polarity under power!

An undefined switch setting (not at one of the end positions) will cause no output voltage.

High voltage output is switched on with HV-ON switch [8] at the front panel. The viability is signalled by the yellow LED [12].

Attention!

If the CONTROL switch [9] is in upper position (manual control), high voltage is generated at HV-output [13] on the front panel with a ramp speed from 500 V/s (hardware ramp) to the set voltage chosen via 10-turn potentiometer [7].

This is also the case, if VME control is switched over to manual control while operating.

If the CONTROL switch [9] is in lower position (DAC), high voltage will be activated only after receiving corresponding VME commands.

On the LCD [1] output voltage in [V] or output current in $[\mu A]$ will be displayed depending on the position of the Measuring switch [3].

For the two channel units, one can choose with Channel switch [2], if channel (A) or channel (B) is displayed.

If working with manual control, output voltage can be set via 10-turn potentiometer [7] in a range from 0 to the set maximal voltage.

If the CONTROL switch [9] is switched over to VME control, the DAC takes over the last set output voltage of manual control. Output voltage can be generated with a programmable ramp speed (software ramp) from 2 to 255 V/s in a range from 0 to the maximal set voltage via VME control.

The maximum output current per channel can be set with a programmable current trip via the interface with the resolution of current measurement. If the output current exceeds the programmable limit, the output voltage will be shut off permanently by the software. Restoring the voltage is possible after reading "Status register 2" and then "Start voltage change" via interface.

Maximum output voltage and current can be selected in 10%-steps with the rotary switches V_{max} [4] and I_{max} [5] (switch dialled to 10 corresponds to 100%) independently of programmable current trip. The output voltage or current which exceed the limits is signalled by the red error LED on the front panel [6].

Function of KILL switch [10]:

Switch to the right position: (ENABLE KILL)

The output voltage will be shut off permanently without ramp on exceeding V_{max} , I_{max} or in the presence of an INHIBIT signal (Low=active) at the INHIBIT input [11]. Restoring the output voltage is possible after operating the switches HV-ON or KILL or reading "Status register 2" and then "Start voltage change" by DAC

control.

Note: When capacitance is effective at the HV-output or when the rate of change of

output voltage is high (hardware ramp) at high load, then the KILL function will be released by the current charging the condenser. In this case use a small rate of output change (software ramp) or select ENABLE KILL not until output voltage is

set voltage.

Switch to the left position:

(DISABLE KILL)

The output voltage will be limited to V_{max} , output current to I_{max} respectively; INHIBIT shuts the output voltage off without ramp, the previous voltage setting will

be restored with hard- or software ramp on INHIBIT no longer being present.

6. VME Interface

Modus: short supervisory access (AM = 0x2D)

short nonprivileged access (AM = 0x29)

Control via VME interface

1st write: set voltage, ramp speed, maximal output current (current trip)

2nd switch: output voltage = set voltage; output voltage = 0

3rd read: set voltage; actual voltage; ramp speed; actual current; current trip

current and voltage hardware limit; status

Front panel switches are having priority over software control.

Manual control

While the unit is operated in manual control mode, VME read cycles are interpreted only. Commands are accepted, but do not result in a change of the output voltage.

Phone ++ 49 351 / 26 996 - 0 Fax ++ 49 351 / 26 996 - 21

Command Execution Time

The command execution time is 2 µs typical.

Base Address

The base address BA is saved in a EEPROM. Setting BA:

- 1. Set both channels of the unit before power requirements (± 12V; + 5V) are activated as follows: => CONTROL switch at MANUELL; => HV-ON switch at OFF; => KILL switch at ENABLE.
- 2. Activate power requirements.
- 3. LCD display shows "A" on the left side and the highbyte of the base address (e.g. "dd") on the right side, with separator flashing in between.
- 4. High-order nibble can be set with channel switch and low-order nibble with measuring switch.
- 5. In case of no change for 10 s or of setting another switch respectively, the chosen base address is saved in EEPROM and the unit is responsive with it.
- 6. Factory setting: BA = 0xDD00

Register addresses

The description for Channel B will be cancelled at the one channel unit.

A7	A6	A5	A4	АЗ	A2	A1	Read	Write

Status register 1 (BA + 0x00)

Channel	Bit	Name	Description	0	1
	D15	ERROR_2	Error on Channel B	Channel ok	Error
	D14	STATV_2	Status V _{Out}	V _{out} stable	V _{out} in change
	D13	TRENDV_2	Ramp up / down	V _{out} falling	V _{out} rising
В	D12	KILL_2	KILL switch setting	Disabled	Enabled
	D11	ON_OFF_2	HV-ON/OFF switch setting	On	Off
	D10	POL_2	Polarity V _{Out}	Negative	Positive
	D9	IN_EX_2	CONTROL switch setting	DAC	Manual
	D8	VZ_2	$V_{Out} = 0$	V _{out} <>0	V _{out} =0
	D7	ERROR_1	Error on Channel A	Channel ok	Error
	D6	STATV_1	Status V _{Out}	V _{out} stable	V _{out} in change
	D5	TRENDV_1	Ramp up / down	V _{out} falling	V _{out} rising
Α	D4	KILL_1	KILL switch setting	Disabled	Enabled
	D3	ON_OFF_1	HV-ON/OFF switch setting	On	Off
	D2	POL_1	Polarity V _{Out}	Negative	Positive
	D1	IN_EX_1	CONTROL switch setting	DAC	Manual
	D0	VZ_1	$V_{Out} = 0$	V _{out} <>0	V _{out} =0

This register is representing the general status of the VHQ.

"Error" is formed by the logic or of REG2ER_, REG1ER_, EXTINH_, RANGE_ and ILIM_ from "Status register 2".

"V_{out}=0" is formed by DAC output = 0 and actual voltage < 5 V.

Set voltage Channel A/B (BA + 0x04 / BA + 0x08)

Set voltage V_{set} from 0 to V_{max} in V. If V_{set} greater then V_{max} (BA + 0x24 / BA + 0x28), V_{set} will be not changed.

Ramp speed Channel A/B (BA + 0x0C / BA + 0x10)

Voltage ramp speed from 2 V/s to 255 V/s. All processor controlled changes in the output voltage are performed at this ramp speed.

Actual voltage Channel A/B (BA + 0x14 / BA + 0x18)

Output voltage Vout of the channels in V.

Actual current Channel A/B (BA + 0x1C / BA + 0x20)

Output current I_{out} of the channels corresponding current resolution.

Hardware limits (BA + 0x24 / BA + 0x28)

D0 .. D3 Maximal output current (I_{max}) in 10 %, hardware setting on the front panel switches D4 .. D7 Maximal output voltage (V_{max}) in 10 %, hardware setting on the front panel switches

D8 .. D15 0

Data ready (BA + 0x2C)

D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	Current B	Voltage B	Current A	Voltage A

The individual bits are set as soon as actual measured data is existing. The bits are reset after the corresponding reading command.

Status register 2 (BA + 0x30)

	Bit	Name	Description	Remark
	D15	REG2ER_2	Quality of output voltage not given at present	
	D14	REG1ER_2	V _{max} or I _{max} is / was exceeded	
Channel	D13	B EXTINH_2 External inhibit was / is active		
	D12	RANGE_2	V _{set} to V _{max} ratio > 1	$D(BA+0x08) > V_{max}$
В	D11	KEY_CHANGED	A frontpanel switch position was changed	ON_OFF_2, IN_EXT_2, KILL_2
	D10	EOP_2	V _{out} has reached set value	End of process_2
	D9	ILIM_2	I _{out} was > I _{max} programmable	Current trip
	D8			
	D7	REG2ER_1	Quality of output voltage not given at present	
	D6	REG1ER_1	V _{max} or I _{max} is / was exceeded	
Channel	D5	EXTINH_1	External inhibit was / is active	
	D4	RANGE_1	V _{set} to V _{max} ratio > 1	$A(BA+0x04) > V_{max}$
Α	D3	KEY_CHANGED	A frontpanel switch position was changed	ON_OFF_1, IN_EXT_1, KILL_1
	D2	EOP_1	V _{out} has reached set value	End of process_1
	D1	ILIM_1	I _{out} was > I _{max} programmable	Current trip
	D0	TOT	Timeout error	New initialisation

The individual bits are set on the occurrence of the event. A general clear is performed after readout.

If the Output voltage was permanently switched off by exceeding V_{max} or I_{max} (ENABLE KILL resp. Current trip), or INHIBIT respectively, the error bits (REG1ER_, EXTINH_, ILIM_) have to be reset by reading " Status register 2" before an output voltage can be set again.

Start voltage change (BA + 0x34 / Ba + 0x38)

A change in the output voltage of set voltage (BA + 0x04 / BA + 0x08) is performed by reading these registers. Writing to the registers stores the data as new set voltage ($V_{set} \le V_{max}$) and starts the voltage change.

The change of output voltage is blocked, if the conditions are unavailable to start voltage change corresponding these description.

Command execution can be checked by reading status register 1 (BA + 0x00). The bits D14 (channel B), D6 (channel A) respectively are set on start of voltage change. Actual voltage reaching the set voltage is flagged by the bits D10, D2 of status register 2 (BA + 0x30) respectively. An interruption of the voltage change (eg. external INHIBIT is active) is also ascertainable.

Module identifier (BA + 0x3C)

D15 .. D0 4 digit serial number, BCD coded

Current software limit (BA + 0x44 / BA + 0x48)

The maximal output current per channel corresponding current resolution. If the output current exceeds the programmable limit, the output voltage will be shut off permanently by the software (Current trip). The Current trip reaction time is lessen to 60 ms.

Writing to the registers with maximal output current = 0, not a current trip will be programmed.

Hardware maximum output current limit (I_{max}) worked independently of programmable current software limit.
