(Dated: July 12, 2002)

## Abstract

A computer program is presented which calculates the elastic and inelastic scattering in intermediate and high energy nuclear collisions. A coupled-channels method is used for Coulomb and nuclear excitations of E1, E2, E3, M1, and M2 multipolarities, respectively. The program applies to an arbitrary nucleus, specified by the spins and energies of the levels and by reduced matrix elements. For given bombarding conditions, the angular distribution of elastic and inelastic scattered particles and angular distributions of gamma-rays from the excited nucleus are computed.

## I. PROGRAM SUMMARY

1. *Title of program:* DWEIKO (Distorted Wave EIKOnal Approximation)

*Program obtainable from:* CPC Program Library, Queen's University of Belfast, N. Ireland

*Computers:* The code has been created on an IBM-PC, but also runs in UNIX machines.

*Operating systems:* WINDOWS or UNIX

*Program language used:* Fortran-77

*Memory required to execute with typical data:* 8 Mbytes of RAM memory and 1 MB of hard disk space

*No. of bits in a word:* 64

*Memory required for test run with typical data:* 1 MB

*No. of bytes in distributed program, including test data, etc.:* 82238

*Distribution format:* ASCII

*Keywords:* Elastic scattering; Coulomb excitation; Relativistic collisions; Coupled-channels; Nuclear excitation

*Nature of physical problem:* The program calculates elastic scattering differential cross sections, probabilities, and cross sections for inelastic scattering in nuclear collisions at intermediate and high energies ( $E_{lab} \geq 50$  MeV/nucleon). It is particularly useful in the analysis of experiments with stable and unstable nuclear beams running at several intermediate-energy heavy ion accelerators around the world.

*Method of solution:* Eikonal wavefunctions are used for the scattering. For each "impact parameter" entering the scattering matrix elements, one solves coupled-channels equations for the time dependent Coulomb + nuclear field expanded into multipoles. A four-point Runge-Kutta procedure is used to solve the coupled-channels equations.

*Typical running time:* Almost all the CPU time is consumed by the solution of the coupled-channels equations. It is about 2 min on a 1GHz Intel P4-processor machine for the inclusion of 5 nuclear states.

## II. LONG WRITE-UP

### A. Introduction

The eikonal approximation is very useful in the study of nucleus-nucleus scattering at high energies. The matrix elements appearing in the scattering processes are of the form

$$\langle \Psi^{(-)}(\mathbf{r}) | \hat{\mathcal{O}} | \Psi^{(+)}(\mathbf{r}) \rangle , \quad (1)$$

where  $\hat{\mathcal{O}}$  is an arbitrary scattering operator, and  $\Psi^{\pm}$  are the scattering wave functions. Using the eikonal approximation for the wave functions one gets [1]

$$\Psi^{(-)*}(\mathbf{r})\Psi^{(+)} \simeq \exp \{ i\mathbf{q}\cdot\mathbf{r} + i\chi(\mathbf{b}) , \} \quad (2)$$

where  $\chi(\mathbf{b})$  is the eikonal phase, given by

$$\chi(\mathbf{b}) = -\frac{1}{\hbar v} \int_{-\infty}^{\infty} dz U_{opt}(\mathbf{r}) . \quad (3)$$

The conditions of validity of the eikonal approximation are: (a) forward scattering, i.e.,  $\theta \ll 1$  radian, and (b) small energy transfers from the bombarding energy to the internal degrees of freedom of the projectile, or target. Both conditions apply perfectly well to nuclear scattering at  $E_{lab} \geq 50$  MeV/nucleon [1].

In the above equation,  $U_{opt}(\mathbf{r})$  is the optical potential, with  $r = \sqrt{b^2 + z^2}$ , where  $b$  can be interpreted as the impact parameter. For the Coulomb part of the optical potential this integral diverges. One solves this by using  $\chi = \chi_N + \chi_C$ , where  $\chi_N$  is given by the equation above without the Coulomb potential and writing the Coulomb eikonal phase,  $\chi_C$  as

$$\chi_C(b) = 2\eta \ln(kb) , \quad (4)$$

where  $\eta = Z_1 Z_2 e^2 / \hbar v$ ,  $Z_1$  and  $Z_2$  are the charges of projectile and target, respectively,  $v$  is their relative velocity,  $k$  their wavenumber in the center of mass system, and  $b$  is the impact parameter. Eq. 4 reproduces the exact Coulomb scattering amplitude when used in the calculation of the elastic scattering with the eikonal approximation [2]. Although it diverges at  $b = 0$ , this does not pose a real problem, since the strong absorption suppresses the scattering at small impact parameters.

The simplification introduced by the eikonal approximation is huge, as one avoids the calculation of scattering wavefunctions by solving numerically the Schrödinger equation for

each partial wave, as is done in Distorted Wave Born Approximation (DWBA) of nuclear scattering at low energies. For a program code of nuclear scattering at low energies, see, e.g., the code DWUCK4 [3].

The eikonal approximation is also valid in relativistic collisions, as it can be derived from relativistic wave equations, e.g., the Klein-Gordon equation [4]. Moreover, since it involves directions transverse to the beam, it is relativistically invariant. The eikonal wavefunction also allows the interpretation of the internal wave function variable  $b$  as an impact parameter. Thus, one can use the concept of classical trajectories, to obtain excitation amplitudes and use them as input to the scattering amplitudes.

At intermediate energy collisions ( $E_{lab} \simeq 50$  MeV/nucleon), one must perform a correction due to the Coulomb deflection of the particle's trajectory. This correction amounts to calculating all elastic and inelastic integrals replacing the asymptotic impact parameter  $b$  by the distance of closest approach in Rutherford orbits, i.e.,

$$kb' = \eta + \sqrt{\eta^2 + k^2 b^2} . \quad (5)$$

This correction leads to a considerable improvement of the eikonal amplitudes for the scattering of heavy systems in collisions at intermediate energies.

As has been shown in ref. [5], the nucleus-nucleus elastic and inelastic scattering at intermediate and high energies is corrected appropriately for relativistic kinematics if one replaces the quantity  $a_0 = Z_1 Z_2 e^2 / mv^2$  (half the distance of closest approach in a head-on collision of point charged particles) by  $a_0 = Z_1 Z_2 e^2 / \gamma m v^2$ , where  $\gamma = (1 - v^2/c^2)^{-1/2}$  is the Lorentz factor. For practical purposes, it is always better to write  $a_0 = \eta \hbar / kv$ , with  $\hbar k = \gamma m v$ , and similarly for the other quantities.

### III. THE OPTICAL POTENTIALS

Usually, the optical potentials used in DWBA calculations are described in terms of Woods-Saxon functions, both for the real and for the imaginary part of the potentials, i.e.,

$$U_{opt} = -V_0 f(r, R_r, a_r) - iW_0 f(r, R_i, a_i) , \quad (6)$$

where  $f(r, R, a) = 1 / \{1 + \exp[(r - R)/a]\}$ . The parameters entering these potentials are fitted to reproduce the elastic scattering data.

In nuclear collisions at intermediate and high energies ( $E_{lab} \geq 50$  MeV/nucleon) the elastic scattering data are very scarce. One has to resort to folding models with effective interactions, at least as a guide for the experimental analysis. Among these models, the M3Y interaction is very popular. It has been shown to work quite reasonably for elastic and inelastic scattering of heavy ions at low and intermediate energy collisions [6, 7].

In its simplest form the M3Y interaction is given by two direct terms with different ranges, and an exchange term represented by a delta interaction:

$$t(s) = A \frac{e^{-\beta_1 s}}{\beta_1 s} + B \frac{e^{-\beta_2 s}}{\beta_2 s} + C \delta(\mathbf{s}) , \quad (7)$$

where  $A=7999$  MeV,  $B = -2134$  MeV,  $C = -276$  MeV  $fm^3$ ,  $\beta_1 = 4$   $fm^{-1}$ , and  $\beta_2 = 2.5$   $fm^{-1}$ . The real part of the optical potential is obtained from a folding of this interaction with the ground state densities,  $\rho_A$  and  $\rho_B$ , of the nuclei A and B:

$$U_{M3Y}(\mathbf{r}) = \int d^3r_1 d^3r_2 \rho_A(\mathbf{r}_1) \rho_B(\mathbf{r}_2) t(s) , \quad (8)$$

with  $\mathbf{s} = \mathbf{r} + \mathbf{r}_2 - \mathbf{r}_1$ . The imaginary part of the optical potential is usually parameterized to be  $\text{Im } U_{opt} = \lambda U_{M3Y}$ , with  $\lambda = 0.6 - 0.8$ .

This double folding M3Y potential yields values at the central region,  $r \simeq 0$ , which are too large as compared to usual optical potentials. However, one has to consider that the nuclear scattering at intermediate and high energies ( $E_{lab} \geq 50$  MeV/nucleon) is mostly peripheral. Central collisions will lead to fragmentation reactions which are not being considered here. Thus, the only requirement here is that the optical potential reproduces well the peripheral processes. This is the case of the M3Y potential and the “t- $\rho\rho$ ” potential discussed below.

Another way to relate the nuclear optical potential to the ground-state densities is to use the “t $\rho\rho$ ” approximation. This approximation has been extensively discussed in the literature [8]. In its simplest version, neglecting the spin-orbit and surface terms, the optical potential for proton-nucleus collisions is given by

$$U_{opt}(\mathbf{r}) = \langle t_{pn} \rangle \rho_n(\mathbf{r}) + \langle t_{pp} \rangle \rho_p(\mathbf{r}) \quad (9)$$

where  $\rho_n$  ( $\rho_p$ ) are the neutron (proton) ground state densities and  $\langle t_{pi} \rangle$  is the (isospin averaged) transition matrix element for nucleon-nucleon scattering at forward directions,

$$t_{pi}(\mathbf{q} = 0) = -\frac{2\pi\hbar^2}{\mu} f_{pi}(\mathbf{q} = 0) = -\frac{\hbar v}{2} \sigma_{pi} (\alpha_{pi} + i) \quad (10)$$

where  $\sigma_{pi}$  is the free proton-nucleon cross section and  $\alpha_{pi}$  is the ratio between the imaginary and the real part of the proton-nucleon scattering amplitude. The basic assumption here is that the scattering is given solely in terms of the forward proton-nucleon scattering amplitude and the local one-body density [8].

For nucleus-nucleus collisions, the extension of this method leads to an optical potential of the form

$$U_{opt}(\mathbf{r}) = \int \langle t_{NN}(\mathbf{q} = 0) \rangle \rho_A(\mathbf{r} - \mathbf{r}') \rho_B(\mathbf{r}') d^3 r', \quad (11)$$

where  $\mathbf{r}$  is the distance between the center-of-mass of the nuclei. In this expression one uses the isospin average

$$\langle t_{NN} \rangle = \frac{Z_1 Z_2 + N_1 N_2}{A_1 A_2} t_{pp} + \frac{Z_1 N_2 + Z_2 N_1}{A_1 A_2} t_{pn}. \quad (12)$$

The parameters of the nucleon-nucleon cross scattering amplitudes for  $E_{lab} \geq 100$  MeV/nucleon are shown in Table II, extracted from ref. [9]. At lower energies one can use the isospin average values of Table II, which well describes the nucleus-nucleus elastic scattering at lower energies.

Table I. Parameters [9] for the nucleon-nucleon amplitude, as given by eq. 13.

The formula 11 can be improved to account for the scattering angle dependence of the nucleon-nucleon amplitudes. A good parametrization [9] for the nucleon-nucleon scattering

amplitude is given by

$$f_{NN}(\mathbf{q}) = \frac{k_{NN}}{4\pi} \sigma_{NN} (i + \alpha_{NN}) e^{-\xi_{NN} \mathbf{q}^2}. \quad (13)$$

The nuclear scattering phase then becomes [1]

$$\chi_N(\mathbf{b}) = \int \int d\mathbf{r} d\mathbf{r}' \rho_1(\mathbf{r}) \gamma_{NN}(|\mathbf{b} - \mathbf{s} - \mathbf{s}'|) \rho_2(\mathbf{r}') \quad (14)$$

where the profile function  $\gamma_{NN}(\mathbf{b})$  is defined in terms of the two-dimensional Fourier transform of the elementary scattering amplitude

$$\gamma_{NN}(\mathbf{b}) = \frac{1}{2\pi i k_{NN}} \int \exp[-i\mathbf{q} \cdot \mathbf{b}] f_{NN}(\mathbf{q}) d\mathbf{q}, \quad (15)$$

and  $\mathbf{s}$ ,  $\mathbf{s}'$  are the projections of the coordinate vectors  $\mathbf{r}$ ,  $\mathbf{r}'$  of the nuclear densities on the plane perpendicular to the  $z$ -axis (beam-axis). For spherically symmetric ground-state densities eq. 14 reduces to the expression

$$\chi_N(b) = \int_0^\infty dq q \tilde{\rho}_A(q) f_{NN}(q) \tilde{\rho}_B(q) J_0(qb), \quad (16)$$

where  $\tilde{\rho}_i(q)$  are the Fourier transforms of the ground state densities.

49	10.4	0.94
85	6.1	1

Table II. Same as in table I, but for lower incident energies. The values are averaged over pp and pn collisions.  $\langle \xi_N \rangle$  is taken as zero at these energies.

The optical potential can also be obtained by using an inversion method of the eikonal phases. These phases might be chosen to fit the experimental data. In this approach, one uses the Abel transform

$$U_{opt}(r) = \frac{\hbar v}{i\pi r} \frac{d}{dr} \int_r^\infty \frac{\chi(b)}{(b^2 - r^2)^{1/2}} r dr. \quad (17)$$

This procedure has been tested in ref. [10] leading to effective potentials which on the tail, where the process takes place, are very close to those obtained by fitting the experimental data. It can also be proved that under certain approximations, and for Gaussian density distributions the potential obtained through eq. 17 coincides with that obtained with the double folding procedure.

#### IV. ELASTIC SCATTERING

The elastic scattering in nucleus-nucleus collisions is a well established tool for the investigation of ground state densities. This is because the optical potential can be related to the ground state densities by means of a folding of the nucleon-nucleon interaction with the nuclear densities of two colliding nuclei. But, as we have seen in the last section, this relationship is not straightforward. It depends on the effective interaction used, a proper treatment of polarization effects, and so on (for a review see, e.g., [8]). At higher bombarding energies ( $E_{Lab} \geq 50$  MeV/nucleon), a direct relationship between the nuclear densities and the optical potential is possible, as long as the effects of multiple nucleon-nucleon scattering can be neglected. The effects of real, or virtual, nuclear excitations should also be considered, especially for radioactive beams, involving small excitation energies.

The calculation of elastic scattering amplitudes using eikonal wavefunctions, eq. 2, is very simple. They are given by [1]

$$f_{el}(\theta) = ik \int_0^\infty db b J_0(qb) \left\{ 1 - \exp \left[ i\chi(b) \right] \right\}, \quad (18)$$

where  $q = 2k \sin(\theta/2)$ , and  $\theta$  is the scattering angle. The elastic scattering cross section is

$$\frac{d\sigma_{el}}{d\Omega} = |f_{el}(\theta)|^2. \quad (19)$$

For numerical purposes, it is convenient to make use of the analytical formula for the Coulomb scattering amplitude. Thus, if one adds and subtracts the Coulomb amplitude,  $f_C(\theta)$  in eq. 18, one gets

$$f_{el}(\theta) = f_C(\theta) + ik \int_0^\infty db b J_0(qb) \exp \left[ i\chi_C(b) \right] \left\{ 1 - \exp \left[ i\chi_N(b) \right] \right\}. \quad (20)$$

The advantage in using this formula is that the term  $1 - \exp \left[ i\chi_N(b) \right]$  becomes zero for impact parameters larger than the sum of the nuclear radii (grazing impact parameter). Thus, the integral needs to be performed only within a small range. In this formula,  $\chi_C$  is given by eq. 4 and

$$f_C(\theta) = -\frac{\eta}{2k \sin^2(\theta/2)} \exp \left\{ -i\eta \ln \left( \sin^2[\theta/2] \right) + i2\phi_0 \right\} \quad (21)$$

where

$$\phi_0 = -\eta C + \sum_{j=0}^{\infty} \left( \frac{\eta}{j+1} - \arctan \frac{\eta}{j+1} \right), \quad (22)$$

and  $C = 0.5772156\dots$  is the Euler's constant.

At high energies the elastic scattering cross section for proton-nucleus collisions is also well described by means of the eikonal approximation [1]. The optical potential for proton-nucleus scattering is assumed to be of the form

$$U_{opt}(r) = U_0(r) + U_S(r) (\mathbf{L}\cdot\mathbf{S}) + U_C(r) \quad (23)$$

where

$$U_0(r) = V_0 f_R(r) + iW_0 f_I(r) + 4 i a_S W_S \frac{d}{dr} f_I(r) \quad (24)$$

and

$$U_S(r) = 2 \left( \frac{\hbar}{m_\pi c} \right)^2 V_S \frac{1}{r} \frac{d}{dr} f_S(r) \quad (25)$$

are the central and spin-orbit part of the potential, respectively, and  $U_C(r)$  is the proton-nucleus Coulomb potential. The Fermi (or Woods-Saxon) functions  $f_i(r)$  are defined as before. The third term in eq. 24 accounts for an increase of probability for nucleon-nucleon collisions at the nuclear surface due to the Pauli principle. The spin-orbit interaction in eq. 25 is usually parametrized in terms of the pion mass,  $m_\pi$ .

In the eikonal approximation, the proton-nucleus elastic scattering cross section is given by [1]

$$\frac{d\sigma_{el}}{d\Omega} = |F(\theta)|^2 + |G(\theta)|^2, \quad (26)$$

where

$$F(\theta) = f_C(\theta) + ik \int_0^\infty db b J_0(qb) \exp[i\chi_C(b)] \left\{ 1 - \exp[i\chi(b)] \cos[kb \chi_S(b)] \right\} \quad (27)$$

and

$$G(\theta) = ik \int_0^\infty db b J_1(qb) \exp[i\chi_C(b) + i\chi(b)] \sin[kb \chi_S(b)]. \quad (28)$$

In the equation above  $q = 2k \sin(\theta/2)$ , where  $\theta$  is the scattering angle,  $\chi = \chi_N + \chi_C$ ,  $J_0$  ( $J_1$ ) is the zero (first) order Bessel function. The eikonal phase  $\chi_S$  is given by

$$\chi_S(\mathbf{b}) = -\frac{1}{\hbar v} \int_{-\infty}^\infty U_S(\mathbf{b}, z) dz. \quad (29)$$

Eqs. 19-29 describe the elastic scattering cross section of  $A$  (projectile) +  $B$  in the center of mass system. In the laboratory the scattering angle is given by [11]

$$\theta_L = \arctan \left\{ \frac{\sin \theta}{\gamma [\cos \theta + \rho g(\rho, \mathcal{E}_1)]} \right\}, \quad (30)$$

where,  $\rho = M_A/M_B$ ,

$$\mathcal{E}_1 = \frac{E_{lab} [\text{MeV/nucleon}]}{m_N c^2}, \quad (31)$$

where  $m_N$  is the nucleon mass, and

$$g(\rho, \mathcal{E}_1) = \frac{1 + \rho(1 + \mathcal{E}_1)}{1 + \mathcal{E}_1 + \rho}, \quad \gamma = \frac{1 + \mathcal{E}_1 + \rho}{\sqrt{(1 + \rho)^2 + 2\rho\mathcal{E}_1}}. \quad (32)$$

$\gamma$  is the relativistic Lorentz factor of the motion of the center of mass system with respect to the laboratory.

The laboratory cross section is

$$\frac{d\sigma_{el}}{d\Omega_L}(\theta_L) = \frac{\left\{ \gamma^2 [\rho g(\rho, \mathcal{E}_1) + \cos \theta]^2 + \sin^2 \theta \right\}^{3/2}}{\gamma [1 + \rho g(\rho, \mathcal{E}_1) \cos \theta]} \frac{d\sigma_{el}}{d\Omega}(\theta). \quad (33)$$

## V. TOTAL NUCLEAR REACTION CROSS SECTIONS

The total nuclear inelastic cross sections (including fragmentation processes) can be easily calculated within the optical limit of the Glauber model [1] is given by

$$\sigma_R = 2\pi \int_0^\infty [1 - T(b)] b db, \quad (34)$$

where  $T(b)$ , the ‘‘transparency function’’, is given by

$$T(b) = \exp[2\text{Im}\chi_N(b)]. \quad (35)$$

## VI. THE SEMICLASSICAL METHOD AND COUPLED-CHANNELS PROBLEM

Coulomb Excitation (CE) in high energy collisions is a well established tool to probe several aspects of nuclear structure [13, 14, 15]. The CE induced by large- $Z$  projectiles and/or targets, often yields large excitation probabilities in grazing collisions. This results from the large nuclear response to the acting electromagnetic fields. As a consequence, a strong coupling between the excited states is expected.

Since there will be very little deflection by the Coulomb field in collisions with impact parameter greater than the grazing one, the excitation amplitudes can be calculated assuming a straight-line trajectory for the projectile. A small Coulomb deflection correction can be used at the end, with the recipe given by eq. 5.

We describe next a method for the calculation of multiple excitation among a finite number of nuclear states. The system of coupled differential equations for the time-dependent amplitudes of the eigenstates of the free nucleus is solved numerically for electric dipole (E1), electric quadrupole (E2), electric octupole (E3), magnetic dipole (M1), and magnetic quadrupole (M2) excitations.

Similarly, one can also calculate the amplitudes for (nuclear) monopole, dipole, quadrupole, and octupole excitations.

In high energy nuclear collisions, the wavelength associated to the projectile-target relative motion is much smaller than the characteristic lengths of the system. It is, therefore, a reasonable approximation to treat  $\mathbf{r}$  as a classical variable  $\mathbf{r}(t)$ , given at each instant by the trajectory followed by the relative motion. At high energies it is also a good approximation to replace this trajectory by a straight line. The intrinsic dynamics can then be handled as a quantum mechanics problem with a time dependent Hamiltonian. This treatment is discussed in full details by Alder and Winther in ref. [12].

The intrinsic state  $|\psi(t)\rangle$  satisfies the Schrödinger equation

$$\{H_0 + V[\mathbf{r}(t)]\} |\psi(t)\rangle = i\hbar \frac{\partial |\psi(t)\rangle}{\partial t}. \quad (36)$$

Above,  $H_0$  is the intrinsic Hamiltonian and  $V$  is the channel-coupling interaction.

Expanding the wave function in the set  $\{|j\rangle; j = 1, N\}$  of eigenstates of  $H_0$ , where  $N$  is the number states included in the coupled-channels (CC) problem, we obtain a set of coupled equations. Taking the scalar product with each of the states  $\langle k|$ , we get

$$i\hbar \dot{a}_k(t) = \sum_{j=1}^N \langle k| V(t) |j\rangle \exp[i(E_k - E_j)t/\hbar] a_j(t), \quad k = 1 \text{ to } N. \quad (37)$$

where  $E_n$  is the energy of the state  $|n\rangle$ . It should be remarked that the amplitudes depend also on the impact parameter  $b$  specifying the classical trajectory followed by the system. For the sake of keeping the notation simple, we do not indicate this dependence explicitly. We write, therefore,  $a_n(t)$  instead of  $a_n(b, t)$ , restoring the notation with  $b$ , or  $t$ , whenever necessary. Since the interaction  $V$  vanishes as  $t \rightarrow \pm\infty$ , the amplitudes have as initial condition  $a_n(t \rightarrow -\infty) = \delta_{n1}$  and they tend to constant values as  $t \rightarrow \infty$ .

A convenient measure of time is given by the dimensionless quantity  $\tau = \gamma vt/b$ , where  $\gamma = (1 - v^2/c^2)^{-1/2}$  is the Lorentz factor for the projectile velocity  $v$ . A convenient measure

of energy is  $E_0 = \gamma \hbar v / b$ . In terms of these quantities the CC equations become

$$\frac{da_k(\tau)}{d\tau} = -i \sum_{j=1}^N \langle k | W(\tau) | j \rangle \exp(i\xi_{kj}\tau) a_j(\tau); \quad W(\tau) = \frac{V(\tau)}{E_0}; \quad \xi_{kj} = \frac{E_k - E_j}{E_0}. \quad (38)$$

The nuclear states are specified by the spin quantum numbers  $I$  and  $M$ . Therefore, the excitation probability of an intrinsic state  $|n\rangle \equiv |I_n, M_n\rangle$  in a collision with impact parameter  $b$  is obtained from an average over the initial orientation ( $M_1$ ), and a sum over the final orientation of the nucleus, respectively:

$$P_n(b) = \frac{1}{2I_1 + 1} \sum_{M_1, M_n} |a_{I_n, M_n}^{M_1}(b)|^2. \quad (39)$$

The total cross section for excitation of the state  $|n\rangle$  is obtained by the classical expression

$$\sigma_n = 2\pi \int P_n(b) b db. \quad (40)$$

## VII. TIME-DEPENDENT ELECTROMAGNETIC INTERACTION

We consider a nucleus 2 which is at rest and a projectile nucleus 1 which moves along the  $z$ -axis. Nucleus 2 is excited from the initial state  $|I_j M_j\rangle$  to the state  $|I_k M_k\rangle$  by the electromagnetic field of nucleus 1. The nuclear states are specified by the spin quantum numbers  $I_j, I_k$  and by the corresponding magnetic quantum numbers  $M_j$  and  $M_k$ . We assume that nucleus 1 moves along a straight-line trajectory with impact parameter  $b$ , which is therefore also the distance of the closest approach between the center of mass of the two nuclei at the time  $t = 0$ . The interaction,  $V_C(t)$ , due to the electromagnetic field of the nucleus 1 acting on the charges and currents nucleus 2 can be expanded into multipoles, as explained in ref. [16]. One has

$$W_C(\tau) = \frac{V_C(\tau)}{E_0} = \sum_{\pi\lambda\mu} W_{\pi\lambda\mu}(\tau), \quad (41)$$

where  $\pi = E, M$  denotes electric and magnetic interactions, respectively, and

$$W_{\pi\lambda\mu}(\tau) = (-1)^{\lambda+1} \frac{Z_1 e}{\hbar v b^\lambda} \frac{1}{\lambda} \sqrt{\frac{2\pi}{(2\lambda+1)!!}} Q_{\pi\lambda\mu}(\xi, \tau) \mathcal{M}(\pi\lambda, -\mu), \quad (42)$$

where  $\mathcal{M}(\pi\lambda, \mu)$  is the multipole moment of order  $\lambda\mu$ ,

$$\mathcal{M}(E\lambda, \mu) = \int d^3r \rho_C(\mathbf{r}) r^\lambda Y_{1\mu}(\mathbf{r}), \quad (43)$$

and

$$\mathcal{M}(M1, \mu) = -\frac{i}{2c} \int d^3r \mathbf{J}_C(\mathbf{r}) \cdot \mathbf{L}(rY_{1\mu}) , \quad (44)$$

$\rho_C(\mathbf{J}_C)$  being the nuclear charge (current). The quantities  $Q_{\pi\lambda\mu}(\tau)$  were calculated in ref. [16, 17], and for the E1, E2, and M1 multipolarities. We will extend the formalism to M2 and E3 excitations.

We use here the notation of Edmonds [18] where the reduced multipole matrix element is defined by

$$\mathcal{M}_{kj}(\pi\lambda, \mu) = (-1)^{I_k - M_k} \begin{pmatrix} I_k & \lambda & I_j \\ -M_k & \mu & M_j \end{pmatrix} \langle I_k || \mathcal{M}(\pi\lambda) || I_j \rangle . \quad (45)$$

To simplify the expression (38) we introduce the dimensionless parameter  $\psi_{kj}^{(\lambda\mu)}$  by the relation

$$\psi_{kj}^{(\lambda\mu)} = (-1)^{\lambda+1} \frac{Z_1 e}{\hbar v b^\lambda} \frac{1}{\lambda} \sqrt{\frac{2\pi}{(2\lambda+1)!!}} \mathcal{M}_{kj}(\pi\lambda, -\mu) .$$

Then we may write eq. 38 in the form

$$\frac{da_k(\tau)}{d\tau} = -i \sum_{r=1}^N \sum_{\pi\lambda\mu} Q_{\pi\lambda\mu}(\xi_{kj}, \tau) \psi_{kj}^{(\lambda\mu)} \exp(i\xi_{kj}\tau) a_j(\tau) . \quad (46)$$

The explicit expressions for eq. 42 can also be obtained by a Fourier transform of the excitation amplitudes found in ref. [15], i.e.,

$$W_{\pi\lambda\mu}(\tau) = \frac{1}{E_0} \cdot \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{i\omega\tau} V_{\pi\lambda\mu}(\omega) d\omega = \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} e^{i\xi\tau} V_{\pi\lambda\mu}(\xi) d\xi, \quad (47)$$

where  $\omega = (E_k - E_j)/\hbar = E_0\xi/\hbar$  (here we omit the sub-indexes  $kj$  for convenience). The expressions for  $V_{\pi\lambda\mu}(\omega)$  are given by [15]

$$V_{\pi\lambda\mu}(\omega) = \frac{Z_1 e}{v\gamma} (-1)^\mu \sqrt{2\lambda+1} \left(\frac{\omega}{c}\right)^\lambda G_{\pi\lambda\mu}\left(\frac{c}{v}\right) K_\mu(\xi) \mathcal{M}(\pi\lambda, -\mu). \quad (48)$$

Using the properties of  $V_{\pi\lambda\mu}(\omega)$  for negative  $\omega$ , one can show that  $V_{\pi\lambda\mu}(-\omega) = (-1)^{\lambda+\mu} V_{\pi\lambda\mu}^*(\omega)$ . Then, one gets from eq. 47

$$W_{\pi\lambda\mu}(\tau) = \frac{Z_1 e}{2\pi\hbar v\gamma} (-1)^\mu \left(\frac{\gamma v}{bc}\right)^\lambda \sqrt{2\lambda+1} G_{\pi\lambda\mu}\left(\frac{c}{v}\right) F_{\lambda\mu}(\xi, \tau) \mathcal{M}(\pi\lambda, -\mu), \quad (49)$$

where

$$\begin{aligned} F_{\lambda\mu}(\xi, \tau) &= 2 \int_0^\infty \cos(\xi\tau) \xi^\lambda K_\mu(\xi) d\xi, & \text{for } \lambda + \mu = \text{even}, \\ &= \frac{2}{i} \int_0^\infty \sin(\xi\tau) \xi^\lambda K_\mu(\xi) d\xi, & \text{for } \lambda + \mu = \text{odd}. \end{aligned} \quad (50)$$

These integrals can be obtained analytically.

Using the functions  $G_{\pi\lambda\mu}(c/v)$  derived in ref. [15] we get explicit closed forms for the E1, E2, E3, M1 and M2 multipolarities,

$$Q_{E10}(\xi, \tau) = -\frac{\sqrt{2}}{\gamma}\tau\phi^3(\tau); \quad Q_{E1\pm 1}(\xi, \tau) = \mp\phi^3(\tau), \quad (51)$$

$$Q_{M10}(\xi, \tau) = 0; \quad Q_{M1\pm 1}(\xi, \tau) = i\left(\frac{v}{c}\right)\phi^3(\tau), \quad (52)$$

$$\begin{aligned} Q_{E20}(\xi, \tau) &= \sqrt{6}(2\tau^2 - 1)\phi^5(\tau), \\ Q_{E2\pm 1}(\xi, \tau) &= \pm 3(2 - \beta^2)\gamma\tau\phi^5(\tau); \quad Q_{E2\pm 2}(\tau) = 3\phi^5(\tau), \end{aligned} \quad (53)$$

$$\begin{aligned} Q_{M20}(\xi, \tau) &= 0, \\ Q_{M2\pm 1}(\xi, \tau) &= -3i\left(\frac{v}{c}\right)\gamma\tau\phi^5(\tau); \quad Q_{M2\pm 2}(\tau) = \mp 3i\left(\frac{v}{c}\right)\phi^5(\tau), \end{aligned} \quad (54)$$

and

$$\begin{aligned} Q_{E30}(\xi, \tau) &= -3\sqrt{\frac{3}{10}}\gamma(5 - \beta^2)\tau(2\tau^2 - 3)\phi^7(\tau), \\ Q_{E3\pm 1}(\xi, \tau) &= \mp\frac{3}{2\sqrt{10}}(15 - 11\beta^2)\gamma^2(4\tau^2 - 1)\phi^7(\tau), \\ Q_{E3\pm 2}(\xi, \tau) &= -\gamma\frac{15}{2}(3 - \beta^2)\tau\phi^7(\tau); \quad Q_{E3\pm 3}(\xi, \tau) = \mp\frac{15}{2}\sqrt{\frac{3}{2}}\phi^7(\tau), \end{aligned} \quad (55)$$

where  $\phi(\tau) = (1 + \tau^2)^{-1/2}$ , and  $\beta = v/c$ .

The fields  $Q_{\pi\lambda\mu}(\xi, \tau)$  peak around  $\tau = 0$ , and decrease rapidly within an interval  $\Delta\tau \simeq 1$ , corresponding to a collisional time  $\Delta t \simeq b/\gamma v$ . This means that numerically one needs to integrate the CC equations in time within an interval of range  $n \times \Delta\tau$  around  $\tau = 0$ , with  $n$  equal to a small integer number.

## VIII. TIME-DEPENDENT NUCLEAR EXCITATION: BOHR-MOTTelson MODEL

In peripheral collisions the nuclear interaction between the ions can also induce excitations. According to the Bohr-Mottelson particle-vibrator coupling model, the matrix element for the transition  $j \rightarrow k$  is given by

$$V_{N(\lambda\mu)}^{(kj)}(\mathbf{r}) \equiv \langle I_k M_k | V_{N(\lambda\mu)} | I_j M_j \rangle = \frac{\delta_\lambda}{\sqrt{2\lambda + 1}} \langle I_k M_k | Y_{\lambda\mu} | I_j M_j \rangle Y_{\lambda\mu}(\hat{\mathbf{r}}) U_\lambda(r) \quad (56)$$

where  $\delta_\lambda$  is the vibrational amplitude and  $U_\lambda(r)$  is the transition potential. To follow the convention of ref. [19], we use  $\alpha_0$  instead of  $\delta_0$  in the equation above.

The transition potentials for nuclear excitations can be related to the optical potential in the elastic channel. This is discussed in details in ref. [19]. The transition potentials for isoscalar excitations are

$$U_0(r) = 3U_{opt}(r) + r \frac{dU_{opt}(r)}{dr} , \quad (57)$$

for monopole,

$$U_1(r) = \frac{dU_{opt}}{dr} + \frac{1}{3} R_0 \frac{d^2U_{opt}}{dr^2} , \quad (58)$$

for dipole, and

$$U_2(r) = \frac{dU_{opt}(r)}{dr} , \quad (59)$$

for quadrupole and octupole modes.  $R_0$  is the nuclear radius at  $\frac{1}{2}$  the central nuclear density.

The deformation length  $\delta_\lambda$  can be directly related to the reduced matrix elements for electromagnetic transitions. Using well-known sum-rules for these matrix elements one finds a relation between the deformation length, and the nuclear sizes and the excitation energies. For isoscalar excitations one obtains [19]

$$\alpha_0^2 = 2\pi \frac{\hbar^2}{m_N} \frac{1}{\langle r^2 \rangle A E_x} , \quad \delta_{\lambda \geq 2}^2 = \frac{2\pi}{3} \frac{\hbar^2}{m_N} \lambda (2\lambda + 1) \frac{1}{A E_x} \quad (60)$$

where  $A$  is the atomic number,  $\langle r^2 \rangle$  is the r.m.s. radius of the nucleus, and  $E_x$  is the excitation energy.

For dipole isovector excitations

$$\delta_1 = \frac{\pi}{2} \frac{\hbar^2}{m_N} \frac{A}{NZ} \frac{1}{E_x} , \quad (61)$$

where  $Z$  ( $N$ ) the charge (neutron) number. The transition potential in this case is modified from eq. 58 to account for the isospin dependence [19]. It is given by

$$U_1(r) = \Lambda \left( \frac{N-Z}{A} \right) \left( \frac{dU_{opt}}{dr} + \frac{1}{3} R_0 \frac{d^2U_{opt}}{dr^2} \right) , \quad (62)$$

where the factor  $\Lambda$  depends on the difference between the proton and the neutron matter radii as

$$\Lambda \frac{2(N-Z)}{3A} = \frac{R_n - R_p}{\frac{1}{2}(R_n + R_p)} = \frac{\Delta R_{np}}{R_0} . \quad (63)$$

Thus, the strength of isovector excitations increases with the difference between the neutron and the proton matter radii. This difference is accentuated for neutron-rich nuclei and should be a good test for the quantity  $\Delta R_{np}$  which enters the above equations.

Notice that the reduced transition probability for electromagnetic transitions is defined by

$$B(\pi\lambda; i \rightarrow j) = \frac{1}{2I_i + 1} |\langle I_j || \mathcal{M}(\pi\lambda) || I_i \rangle|^2 . \quad (64)$$

These can be related to the deformation parameters by

$$B(E0) = \left[ \frac{3ZeR_0^2}{10\pi} \right]^2 \alpha_0^2 , \quad B(E1) = \left[ \frac{3}{4\pi} \frac{NZ}{A} e \right]^2 \delta_1^2 , \quad (65)$$

and

$$B(E\lambda)_{\lambda \geq 2} = \left[ \frac{3}{4\pi} ZeR_0^{\lambda-1} \right]^2 \delta_\lambda^2 . \quad (66)$$

The time dependence of the matrix elements above can be obtained by making a Lorentz boost. One gets

$$\begin{aligned} V_{N(\lambda\mu)}^{(kj)}(t) &\equiv \langle I_k M_k | U | I_j M_j \rangle \\ &= \gamma \frac{\delta_\lambda}{\sqrt{2\lambda + 1}} \langle I_k M_k | Y_{\lambda\mu} | I_j M_j \rangle Y_{\lambda\mu}(\theta(t), 0) U_\lambda[r(t)] , \end{aligned} \quad (67)$$

where  $r(t) = \sqrt{b^2 + \gamma^2 v^2 t^2} = 1/(b\phi(\tau))$ ,  $\theta = \tau\phi(\tau)$ , and

$$\langle I_k M_k | Y_{\lambda\mu} | I_j M_j \rangle = (-1)^{I_k - M_k} \left[ \frac{(2I_k + 1)(2\lambda + 1)}{4\pi(2I_j + 1)} \right]^{1/2} \begin{pmatrix} I_k & \lambda & I_j \\ -M_k & \mu & M_j \end{pmatrix} \begin{pmatrix} I_k & \lambda & I_j \\ 0 & 0 & 0 \end{pmatrix} . \quad (68)$$

To put it in the same notation as in eq. (46), we define  $Q_{N\lambda\mu}^{(kj)}(\tau) = V_{N(\lambda\mu)}^{(kj)}(t)/E_0$ , and the coupled-channels equations become

$$\frac{da_k(\tau)}{d\tau} = -i \sum_{j=1}^N \sum_{\lambda\mu} \sum_{\pi} \left[ Q_{N\lambda\mu}^{(kj)}(\xi_{kj}, \tau) + Q_{C\pi\lambda\mu}(\xi_{kj}, \tau) \right] \psi_{kj}^{(\lambda)} \exp(i\xi_{kj}\tau) a_j(\tau) . \quad (69)$$

## IX. ABSORPTION AT SMALL IMPACT PARAMETERS

If the optical potential  $U_{opt}(\mathbf{r})$  is known, the absorption probability in grazing collisions can be calculated in the eikonal approximation as

$$A(b) = \exp \left[ \frac{2}{\hbar v} \int_{-\infty}^{\infty} \text{Im} [U_{opt}(\mathbf{r})] dz \right] , \quad (70)$$

where  $r = \sqrt{b^2 + z^2}$ . If the optical potential is not known, the absorption probability can be calculated from the optical limit of the Glauber theory of multiple scattering (also from the “ $t$ - $\rho\rho$ ” approximation), which yields:

$$A(b) = \exp \left\{ -\sigma_{NN} \int_{-\infty}^{\infty} \left[ \int \rho_1(\mathbf{r}') \rho_2(\mathbf{r} - \mathbf{r}') d^3r' \right] dz \right\} . \quad (71)$$

where  $\sigma_{NN}$  is the nucleon-nucleon cross section and  $\rho_i$  is the ground state density of the nucleus  $i$ . For stable nuclei, these densities are taken from the droplet model densities of Myers and Swiatecki [20], but can be easily replaced by more realistic densities.

Including absorption, the total cross section for excitation of the state  $|n\rangle$  is obtained by

$$\sigma_n = 2\pi \int A(b) P_n(b) b db . \quad (72)$$

## X. ANGULAR DISTRIBUTION OF INELASTICALLY SCATTERED PARTICLES

The angular distribution of the inelastically scattered particles can be obtained from the semiclassical amplitudes,  $a_{I_n, M_n}^{M_1}(b)$ , described in section VII. For the excitation of a generic state  $|n\rangle$ , it is given by [21]

$$f_{inel}^\mu(\theta) = ik \int_0^\infty db b J_\mu(qb) e^{i\chi(b)} a_\mu(b) , \quad (73)$$

where we simplified the notation:  $a_\mu \equiv a_{I_n, M_n}^{M_1}$ , with  $\mu = M_n - M_1$ .

For collisions at high energies, the integrand of eq. 73 oscillates wildly at the relevant impact parameters and scattering angles. One can use the approximation

$$\begin{aligned} J_\mu(qb) &\simeq \sqrt{\frac{2}{\pi qb}} \cos \left( qb - \frac{\pi\mu}{2} - \frac{\pi}{4} \right) \\ &= \frac{1}{\sqrt{2\pi qb}} \left\{ e^{iqb} e^{-i\pi(\mu+1/2)/2} + e^{-iqb} e^{i\pi(\mu+1/2)/2} \right\} , \end{aligned} \quad (74)$$

together with the stationary-phase approximation

$$\int G(x) e^{i\phi(x)} dx \simeq \left( \frac{2\pi i}{\phi''(x_0)} \right)^{1/2} G(x_0) e^{i\phi(x_0)} , \quad (75)$$

where  $x_0$  is the point of stationary phase, satisfying

$$\phi'(x_0) = 0 . \quad (76)$$

This approximation is valid for a slowly varying function  $G(x)$ .

Only the second term in the brackets of eq. 74 will have a positive ( $b = b_0 > 0$ ) stationary point, and eq. 73 becomes

$$f_{inel}^\mu(\theta) \simeq i \frac{k}{\sqrt{q}} \left( \frac{i}{\phi''(x_0)} \right)^{1/2} \sqrt{b_0} \exp[\text{Im}\chi_N(b_0)] \exp[i\chi(b_0) + i\pi(m + 1/2)/2] a_\mu(b_0), \quad (77)$$

where

$$\phi = -qb + 2\eta \ln(kb) + \text{Re}\chi'_N(b), \quad (78)$$

and  $b_0$ , the “classical impact parameter” is the solution of

$$-q + \frac{2\eta}{b_0} + \text{Re}\chi'_N(b_0) = 0. \quad (79)$$

This equation has 2 solutions: (a) one corresponding to *close* collisions, (b) and another corresponding to *far* collisions. These are collisions passing by one side and the opposite side of the target, but leading to the same scattering angle. They thus lead to interferences in the cross sections.

In collisions at high energies, the inelastic scattering is dominated by close collisions and, moreover, one can neglect the third term in eq. 79. The condition  $\phi'(b_0) = 0$  implies

$$b_0 = \frac{2\eta}{q} = \frac{a_0}{\sin(\theta/2)}, \quad a_0 = \frac{Z_1 Z_2 e^2}{2kv}, \quad \text{and} \quad \phi''(b_0) = -\frac{2\eta}{b_0^2} = -\frac{q^2}{2\eta}. \quad (80)$$

We observe that the relation 80 is the same [with  $\cot(\theta/2) \simeq \sin^{-1}(\theta/2)$ ] as that between the impact parameter and the deflection angle of a particle following a classical Rutherford trajectory.

Inserting these results in eq. 73, and using

$$\frac{d\sigma_{inel}}{d\Omega} = |f_{inel}|^2, \quad (81)$$

one gets for the inelastic scattering leading to the excitation of the state  $|n\rangle$

$$\frac{d\sigma_{inel}^{(n)}}{d\Omega} = \left( \frac{4\eta^2 k^2}{q^4} \right) \frac{1}{2I_1 + 1} \sum_{M_1, M_n} |a_{I_n, M_n}^{M_1}(b_0)|^2 e^{2\text{Im}\chi_N(b_0)}. \quad (82)$$

One can easily see that the factor  $4\eta^2 k^2/q^4$  is the Rutherford cross section.

The above results show that the description of the inelastic scattering in terms of the eikonal approximation reproduces the expected result, i.e., that the excitation cross sections are determined by the product of the Rutherford cross sections and the excitation probabilities. This is a commonly used procedure in Coulomb excitation at low energies.

If the nuclear excitation is as strong as the Coulomb excitation, the impact parameters have to be chosen according to the solution of eq. 78 and the scattering amplitude is given by eq. 77.

The cross sections in the laboratory system are obtained according to the same prescription as described at the end of section IV.

## XI. ANGULAR DISTRIBUTION OF $\gamma$ -RAYS

After the excitation, the nuclear state  $|I_f\rangle$  can decay by gamma emission to another state  $|I_g\rangle$ . Complications arise from the fact that the nuclear levels are not only populated by Coulomb excitation, but also by conversion and  $\gamma$ -transitions cascading down from higher states (see figure 1(a)). To compute the angular distributions one must know the parameters  $\Delta_l(i \rightarrow j)$  and  $\epsilon_l(i \rightarrow j)$  for  $l \geq 1$ ,

$$\epsilon_l^2(i \rightarrow j) = \alpha_l(i \rightarrow j) \Delta_l^2(i \rightarrow j), \quad (83)$$

where  $\alpha_l$  is the total  $l$ -pole conversion coefficient, and

$$\Delta_{\pi l} = \left[ \frac{8\pi(l+1)}{l[(2l+1)!!]^2} \frac{1}{\hbar} \left(\frac{\omega}{c}\right)^{2l+1} \right]^{1/2} (2I_j+1)^{-1/2} \langle I_j \| i^{s(l)} \mathcal{M}(\pi l) \| I_i \rangle, \quad (84)$$

with  $s(l) = l$  for electric ( $\pi = E$ ) and  $s(l) = l+1$  for magnetic ( $\pi = M$ ) transitions. The square of  $\Delta_{\pi l}$  is the  $l$ -pole  $\gamma$ -transition rate (in  $\text{sec}^{-1}$ ).

As for the non-relativistic case [12, 22], the angular distributions of gamma rays following the excitation depend on the frame of reference used. In our notation, the z-axis corresponds to the beam axis, and the statistical tensors are given by (we use the notation of [12, 22])

$$\begin{aligned} \alpha_{k\kappa}^{(0)}(f) &= \frac{(2I_f+1)^{1/2}}{(2I_1+1)} \sum_{M_f=-(M'_f+\kappa), M'_f} (-1)^{I_f+M_f} \begin{pmatrix} I_f & I_f & k \\ -M_f & M'_f & \kappa \end{pmatrix} \\ &\times \sum_{M_1} a_{I_f M'_f}^*(M_1) a_{I_f M_f}(M_1), \end{aligned} \quad (85)$$

where  $f$  is the state from which the gamma ray is emitted, and 1 denotes the initial state of the nucleus, before the excitation. To calculate the angular distributions of the gamma rays one needs the statistical tensors for  $k = 0, 2, 4$  and  $-k \leq \kappa \leq k$  (see [12, 22]).

Instead of the diagram of figure 1(a), we will consider here the much simpler situation in which the  $\gamma$ -ray is emitted directly from the final excited state  $f$  to a lower state  $g$ , which

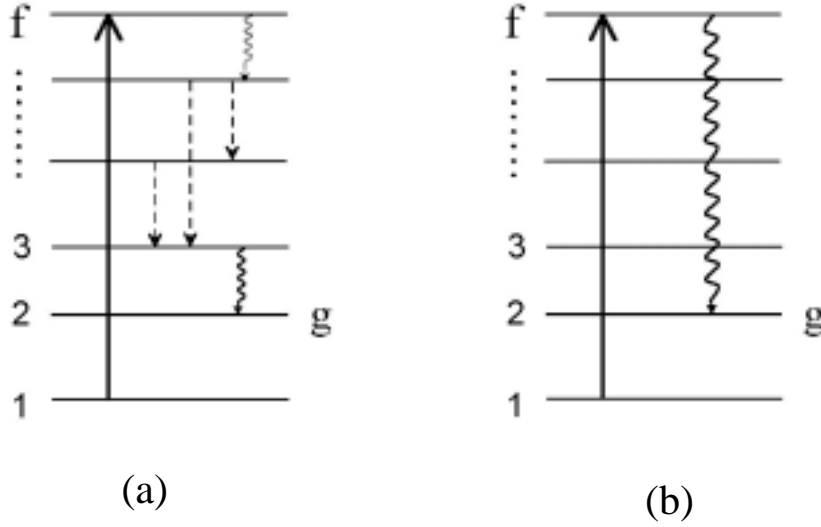

FIG. 1: Schematic description of a nuclear excitation (solid line) followed by  $\gamma$ -decay (solid wavy line). (a) The dashed lines are transitions due to internal conversion (unobserved). The dashed wavy line is an unobserved  $\gamma$ -decay. (b) Direct emission of an observed gamma ray.

is observed experimentally (see figure 1(b)). The probability amplitude for this process is

$$a_{i \rightarrow f \rightarrow g} = \sum_{M_f} a_{i \rightarrow f} \langle I_g M_g \mathbf{k} \sigma | H_\gamma | I_f M_f \rangle, \quad (86)$$

where  $\langle I_g M_g \mathbf{k} \sigma | H_\gamma | I_f M_f \rangle$  is the matrix element for the transition  $f \rightarrow g$  due to the emission of a photon with momentum  $\mathbf{k}$  and polarization  $\sigma$ . The operator  $H_\gamma$  accounts for this transition. The angular dependence of the  $\gamma$ -rays is given explicitly by the spherical coordinates  $\theta$  and  $\phi$  of the vector  $\mathbf{k}$ .

Since the angular emission probability will be normalized to unity, we can drop constant factors and write it as (an average over initial spins is included)

$$W(\theta) = \sum_{M_i, M_g, \sigma} |a_{i \rightarrow g}|^2 = \sum_{M_i, M_g, \sigma} \left| \sum_{M_f} a_{i \rightarrow f} \langle I_g M_g \mathbf{k} \sigma | H_\gamma | I_f M_f \rangle \right|^2. \quad (87)$$

The transition operator  $H_\gamma$  can be written as

$$H_\gamma = \sum_{lm} H_\gamma^{(lm)} = \sum_{lm} \hat{\mathcal{O}}_{lm}^{(nuc)} \otimes \hat{\mathcal{O}}_{lm}^{(\gamma)}, \quad (88)$$

where the first operator in the sum acts between nuclear states, whereas the second operator acts between photon states of well defined angular momentum,  $l, m$ .

Expanding the photon state  $|\mathbf{k}\sigma\rangle$  in a complete set  $|lm\rangle$  of the photon angular momentum, and using the Wigner-Eckart theorem (angular momentum notation of ref. [18]), one gets

$$\begin{aligned} \langle I_g M_g \mathbf{k}\sigma | H_\gamma | I_f M_f \rangle &= \sum_{l,m} \langle \mathbf{k}\sigma | lm \rangle \langle I_g M_g | H_\gamma^{(lm)} | I_f M_f \rangle \\ &= (-1)^{I_f - M_f} \sum_{l,m} \begin{pmatrix} I_f & l & I_g \\ -M_f & m & M_g \end{pmatrix} \langle \mathbf{k}\sigma | lm \rangle \langle I_g \| H_\gamma^{(l)} \| I_f \rangle. \end{aligned} \quad (89)$$

One can rewrite  $|\mathbf{k}\sigma\rangle$  in terms of  $|\mathbf{z}\sigma\rangle$ , i.e., in terms of a photon propagating in the z-direction. This is accomplished by rotating  $|\mathbf{k}\sigma\rangle$  to the z-axis, using of the rotation matrix,  $D_{mm'}^l$ , i.e.,

$$\langle \mathbf{k}\sigma | lm \rangle = \sum_{m'} D_{mm'}^l(\mathbf{z} \rightarrow \mathbf{k}) \langle \mathbf{z}\sigma | lm' \rangle. \quad (90)$$

Expanding the photon field in terms of angular momentum eigenfunctions, one can show that [23, 24]

$$\langle \mathbf{z}\sigma | lm\pi \rangle = \begin{cases} \sqrt{\frac{2l+1}{2}} \delta_{\sigma m} & \text{for } \pi = E \\ \sqrt{\frac{2l+1}{2}} \sigma \delta_{\sigma m} & \text{for } \pi = M. \end{cases} \quad (91)$$

One has now to express the operator  $\hat{\mathcal{O}}_{l'm'}^{(\gamma)}$  in eq. 88 in terms of the electric and magnetic multipole parts of the photon field. This problem is tedious but straightforward [25]. Inserting eqs. 90 and 91 in eq. 89, yields (neglecting constant factors)

$$\begin{aligned} \langle I_g M_g \mathbf{k}\sigma | H_\gamma | I_f M_f \rangle &= \sum_{l,m} (-1)^{I_g - l + M_f} \sqrt{(2l+1)(2I_f+1)} \begin{pmatrix} I_g & l & I_f \\ M_g & m & -M_f \end{pmatrix} \\ &\times D_{m\sigma}^l(\mathbf{z} \rightarrow \mathbf{k}) [\Delta_{El} + \sigma \Delta_{Ml}], \end{aligned} \quad (92)$$

where  $\Delta_{\pi l}$  is given by eq. 84.

Inserting 92 in eq. 87 one gets a series of sums over the intermediate values of the angular momenta

$$\begin{aligned} W(\theta) &= \sum_{\substack{M_i, M_g, \sigma, M_f, \\ M'_f, l, m, l', m'}} a_{i \rightarrow f} a_{i \rightarrow f'}^* \sqrt{(2l+1)(2l'+1)(2I_f+1)} \begin{pmatrix} I_g & l & I_f \\ M_g & m & -M_f \end{pmatrix} \\ &\times (-1)^{M_f + M'_f - l - l'} \begin{pmatrix} I_g & l' & I_f \\ M_g & m' & -M'_f \end{pmatrix} D_{m\sigma}^l [D_{m'\sigma}^{l'}]^* \Delta_l \Delta_{l'}^*, \end{aligned} \quad (93)$$

where  $\Delta_l = \Delta_{El} + l\Delta_{Ml}$ . The product  $\Delta_l \Delta_{l'}^*$  is always real since  $(-1)^{s(l)} = \Pi$  (the parity).

Assuming that the particles are detected symmetrically around the z-axis one can integrate over  $\phi_{particle}$ , what is equivalent to integrating, or averaging, over  $\phi_\gamma$ . This yields the following integral

$$\int d\phi D_{m\sigma}^l [D_{m'\sigma}^{l'}]^* = \delta_{mm'} (-1)^{m-\sigma} \sum_j \frac{2j+1}{\sqrt{4\pi}} \begin{pmatrix} l & j & l' \\ m & 0 & -m \end{pmatrix} \begin{pmatrix} l & j & l' \\ \sigma & 0 & -\sigma \end{pmatrix} P_j(\cos\theta). \quad (94)$$

To simplify further eq. 93 we use (see ref. [12], p. 441, eq. II.A.61)

$$\begin{aligned} & \sum_{M_g} \begin{pmatrix} I_g & l & I_f \\ M_g & m & -M_f \end{pmatrix} \begin{pmatrix} I_g & l' & I'_f \\ M_g & m' & -M'_f \end{pmatrix} \\ &= (-1)^{2l'-I_g} \sum_{k,\kappa} (-1)^{k+m-M'_f} (2k+1) \begin{pmatrix} l & l' & k \\ m & -m' & \kappa \end{pmatrix} \begin{pmatrix} I_f & I'_f & k \\ M_f & -M'_f & \kappa \end{pmatrix} \left\{ \begin{matrix} l & l' & k \\ I'_f & I_f & I_g \end{matrix} \right\} \end{aligned} \quad (95)$$

and

$$\sum_{\sigma=(-1,1)} \begin{pmatrix} l & j & l' \\ \sigma & 0 & -\sigma \end{pmatrix} \Delta_{\pi l} \Delta_{\pi l'}^* = \begin{cases} 2 \begin{pmatrix} l & j & l' \\ 1 & 0 & -1 \end{pmatrix} \Delta_{\pi l} \Delta_{\pi l'}^*, & \text{for } j = \text{even} \\ 0, & \text{for } j = \text{odd}, \end{cases}$$

where use has been made of the parity selection rule

$$\Pi_1 \Pi_2 = \begin{cases} (-1)^l, & \text{for electric transitions} \\ (-1)^{l+1}, & \text{for magnetic transitions.} \end{cases}$$

Eq. 93 becomes

$$\begin{aligned} W(\theta) &= \sum_{\substack{M_i, k, \kappa, M_f, M'_f, \\ l, l', m, m'}} (-1)^{2m'+k+M_f} a_{i \rightarrow f} a_{i \rightarrow f'}^* \sqrt{(2l+1)(2l'+1)(2I_f+1)} \\ &\times (2j+1)(2k+1) \begin{pmatrix} I_f & I_f & k \\ M_f & -M'_f & \kappa \end{pmatrix} \begin{pmatrix} I_f & l' & k \\ M_f & -m' & \kappa \end{pmatrix} \\ &\times \begin{pmatrix} l & j & l' \\ 1 & 0 & -1 \end{pmatrix} \begin{pmatrix} l & j & l' \\ m & 0 & -m' \end{pmatrix} \left\{ \begin{matrix} l & l' & k \\ I'_f & I_f & I_g \end{matrix} \right\} \Delta_l \Delta_{l'}^* P_j(\cos\theta). \end{aligned} \quad (96)$$

Using

$$\sum_{m, m'} (-1)^{2m'} \begin{pmatrix} l & j & l' \\ m & 0 & -m' \end{pmatrix} \begin{pmatrix} l & j & l' \\ 1 & 0 & -1 \end{pmatrix} = (-1)^{l+l'+k} \frac{1}{2k+1} \delta_{kj} \delta_{\kappa 0},$$

one gets

$$W(\theta) = \sum_{\substack{k=\text{even}, M_i, \\ M_f, l, l'}} (-1)^{l+l'+k} \sqrt{(2l+1)(2l'+1)(2I_f+1)(2k+1)} |a_{i \rightarrow f}|^2 \\ \times \begin{pmatrix} I_f & I_f & k \\ M_f & -M_f & 0 \end{pmatrix} \begin{pmatrix} l & j & l' \\ 1 & 0 & -1 \end{pmatrix} \left\{ \begin{matrix} l & l' & k \\ I_f & I_f & I_g \end{matrix} \right\} \Delta_l \Delta_{l'}^* P_j(\cos \theta),$$

or in a more compact form

$$W(\theta) = \sum_{\substack{k=\text{even}, M_i, M_f, \\ l, l'}} (-1)^{M_f} |a_{i \rightarrow f}|^2 F_k(l, l', I_g, I_f) \begin{pmatrix} I_f & I_f & k \\ M_f & -M_f & 0 \end{pmatrix} \sqrt{2k+1} P_k(\cos \theta) \Delta_l \Delta_{l'}^*, \quad (97)$$

where

$$F_k(l, l', I_g, I_f) = (-1)^{I_f - I_g - 1} \sqrt{(2l+1)(2l'+1)(2I_f+1)(2k+1)} \\ \times \begin{pmatrix} l & l' & k \\ 1 & -1 & 0 \end{pmatrix} \left\{ \begin{matrix} l & l' & k \\ I_f & I_f & I_g \end{matrix} \right\}. \quad (98)$$

The angular distribution of  $\gamma$ -rays described above is in the reference frame of the excited nucleus. To obtain the distribution in the laboratory one has to perform the transformation

$$\theta_L = \arctan \left\{ \frac{\sin \theta}{\gamma [\cos \theta + \beta]} \right\}, \quad (99)$$

and

$$W(\theta_L) = \gamma^2 (1 + \beta \cos \theta)^2 W(\theta), \quad (100)$$

where  $\gamma$  is given by eq. 32, and  $\beta = \sqrt{1 + 1/\gamma^2}$ . The photon energy in the laboratory is  $E_L^{ph} = \gamma E_{cm}^{ph} (1 + \beta \cos \theta)$ .

## A. Computer program and user's manual

All nuclear quantities, either known from experiments or calculated from a model, as well as the conditions realized in the experiment, are explicitly specified as input parameters. The program DWEIKO then computes the optical potentials (if required), differential cross section for elastic scattering, and Coulomb + nuclear excitation probabilities and cross sections, as well as the angular distribution of the  $\gamma$ -rays.

The units used in the program are fm (Fermis) for distances and MeV for energies. The output cross sections are given in millibarns.

### 1. *Input parameters*

To avoid exceeding use of computer's memory, the file DWEIKO.DIM contains the dimension of the arrays and sets in the maximum number of levels (NMAX), maximum total number of magnetic substates, (NSTMAX), maximum number of impact parameters (NBMAX), and maximum number of coordinates points used in the optical potentials and absorption factors, (NGRID).

Most integrals are performed by the 1/3-Simpson's integration rule. It is required that NGRID be a *even* number, since an extra point (origin) is generated in the program.

The input file allows for comment lines. These should start with a '#' sign.

The file DWEIKO.IN contains all other input parameters. These are

1. AP, ZP, AT, ZT, which are the projectile and the target mass and charge numbers, respectively.
2. ECA, the bombarding energy per nucleon in MeV.
3. EX(j) and SPIN(j): the energy and spins of the individual states j.
4. MATE1(j,k), MATE2(j,k), MATE3 (j,k), MATM1(j,k), MATM2(j,k) the reduced matrix elements for E1, E2, E3 and M1, M2 excitations,  $j \rightarrow k$ , (as defined in (45)), in  $e$  fm (E1,M1),  $e$  fm<sup>2</sup> (E2,M2), and  $e$  fm<sup>4</sup> (E3) units.
5. F(0,j), F(1,j), F(2,j), F(3,j), the fractions of sum rule of the deformation parameters for monopole, dipole, quadrupole, and octupole nuclear excitations, entering eq. (67).

To simplify the input, the deformation parameters are calculated internally in DWEIKO using the sum rules 60-63, with  $E_x$  replaced by the energy of the corresponding state, EX(j).

The user needs to enter the fraction of those sum rules exhausted by the state j, i.e., the program uses  $\delta'_\lambda = f_\lambda \delta_\lambda$ , with ( $0 \leq f_\lambda \leq 1$ ) entered by the user, and  $\delta_\lambda$  given by eqs. 60-63.

The input cards in file DWEIKO.IN are organized as following:

1. AP, ZP, AT, ZT, ECA, E<sub>lab</sub> [MeV/u].

Charges and masses (AP,ZP,AT,ZT), bombarding energy per nucleon (E<sub>lab</sub>) in MeV/nucleon.

2. IW, IOPM, IOELAS, IOINEL, IOGAM

IW=0(1) for projectile (target) excitation.

IOPM=1(0) for output (none) of optical model potentials.

IOELAS=(0)[1]2 for (no output) [center of mass] laboratory elastic scattering cross section.

IOINEL=(0)[1]2 for (no output) [center of mass] laboratory inelastic scattering cross section.

IOGAM=(0)[1]2 for (no output) [output of statistical tensors] output of gamma-ray angular distributions.

The statistical tensors are calculated for each impact parameter, so that one can use them in the computation of  $dP_{\gamma N \rightarrow M}(b)/d\Omega_{\gamma} = P_N(b) \cdot dW_{\gamma N \rightarrow M}/d\Omega_{\gamma}$ . If IW = 0, a transformation to the laboratory system is performed.

### 3. NB, ACCUR, BMIN, IOB

NB=number of impact parameter points.

ACCUR = accuracy required for the time integration of the CC-equations for each impact parameter. A reasonable value is ACCUR = 0.001, i.e., 0.1%.

BMIN=minimum impact parameter (enter 0 for default. The program will integrate from  $b \simeq 0$ , with strong absorption included).

IOB=1(0) prints (does not print) out impact parameter probabilities.

### 4. IOPW, IOPNUC

IOPW is a switch for the optical potential model (OPM).

IOPW=0 (no OPM), 1 (Woods-Saxon), 2 (read), 3 (t- $\rho\rho$  folding potential), 4 (M3Y folding potential).

IOPNUC=0 (no nuclear), 1 (vibrational excitations).

If the optical potential is provided (IOPW=2), it should be stored in 'optw.in' in rows of R x Real[U(R)] x Imag[U(R)]. The program makes an interpolation to obtain intermediate values.

The first line in 'optw.in' is the number of rows (maximum=NGRID).

### 5. V0 [MeV], r0 [fm], d [fm], VI [MeV], r0\_I [fm], dI [fm]

If IOPW=1, enter  $V_0$  [VI] = real [imaginary] part ( $>0$ ) of Woods-Saxon potential,  $r_0$  [r0\_L] = radius parameter ( $R = r_0 * (AP^{1/3} + AT^{1/3})$ ),  $d$  [dI] = diffuseness,

If IOPW is not equal to 1, place a '#' sign at the beginning of this line, or delete it.

6.  $VS_0$  [MeV],  $r_{0\_S}$  [fm],  $dS$  [fm],  $V\_surf$  [fm],  $a\_surf$  [fm]

If IOPW=1 and AP, or AT, equal to one (proton), enter here spin-orbit part. If not, place a '#' sign at the beginning of this line, or delete it.

$VS_0$  = depth parameter of the spin-orbit potential ( $>0$ ),  $r_{0\_S}$  = radius parameter,  $dS$  = diffuseness,  $V\_surf$  = depth parameter of the surface potential ( $>0$ ),  $a\_surf$  = diffuseness,

7. Wrat

If IOPW=4, enter Wrat = ratio of imaginary to real part of M3Y interaction.

If IOPW is not equal to 4, place a '#' sign at the beginning of this line, or delete it.

8. THMAX, NTHETA

If IOELAS=1,2 or IOINEL=1,2 enter here THMAX, maximum angle (in degrees and in the center of mass), and NTHETA, the number of points in the scattering angle.

If IOELAS or IOINEL are not 1, or 2, place a '#' sign at the beginning of this line, or delete it.

9. JINEL

If IOINEL=1 enter the state (JINEL) for the inelastic angular distribution. Choosing '0' adds the contributions of all states.

If IOINEL is not 1, or 2 place a '#' sign at the beginning of this line, or delete it.

10. NST

NST is the number of nuclear levels.

11. I, EX(I), SPIN(I)

Input of state labels (I), energy EX(I), and angular momentum SPIN(I). I ranges from 1 to NST and should be listed in increasing value of energies.

12. I, J, E1[e fm], E2[e fm<sup>2</sup>], E3[e fm<sup>3</sup>], M1[e fm], M2[e fm<sup>2</sup>]

Reduced matrix elements for E1, E2, E3, M1 and M2 excitations:  $\langle I_j || O(E/M; L) || I_i \rangle$ ,  $j \geq i$ , for the electromagnetic transitions. Matrices for reorientation effects,  $i \rightarrow i$ , can also be given.

Add a row of zeros at the end of this list.

13. J, F0, F1, F2, F3

If IOPNUC=1 enter sum rule fraction of nuclear deformation parameters for monopole, dipole, quadrupole nuclear excitations (ALPHA0,DELTE1,DELTE2,DELTE3) for each excited state J.

If IOPNUC=0 insert a comment card ('#') in front of each entry row, or delete them.

14. IFF, IGG, THMIN, THMAX, NTHETA

If IOGAM=2, enter IFF,IGG = initial and final states (IFF > IGG) for the gamma transition.

THMIN, THMAX = minimum and maximum values of gamma-ray angles (in degrees) in the laboratory frame.

NTHETA = number of angle points (< NGRID).

## 2. Computer program

The program starts with a catalogue of the nuclear levels by doing a correspondence of integers to each magnetic substate.  $J = 1$  corresponds to the lowest energy level, with the magnetic quantum number  $M_1 = -I_1$ .  $J$  increases with  $M_1$  and so on for the subsequent levels.

A mesh in impact parameter is done, reserving half of the impact parameter points, i.e.,  $NB/2$ , to a finer mesh around the grazing impact parameter, defined as  $b_0 = 1.2 (A_P^{1/3} + A_T^{1/3})$  fm. The interval  $b_0/2 \text{ fm} \leq b \leq 3b_0/2 \text{ fm}$  is covered by this mesh. A second mesh, with the other half of points, extends from  $b = 3b_0/2 \text{ fm}$  to  $b = 200 \text{ fm}$ . Except for the very low excitation energies ( $E_j \ll 1 \text{ MeV}$ ), combined with very large bombarding energies ( $\gamma \gg 1$ ), this upper value of  $b$  corresponds to very small excitation probabilities, and the calculation can be safely stopped. The reason for a finer mesh at small impact

parameters is to get a good accuracy at the region where both nuclear, Coulomb, and absorption factors play equally important roles. At large impact parameters the probabilities fall off smoothly with  $b$ , justifying a wider integration step.

A mesh of NGRID points in polar coordinates is implemented to calculate the nuclear excitation potentials and absorption factors, according to the equations presented in sections 2.2 and 2.3. The first and second derivatives of the optical potentials are calculated by the routine DERIVATIVE. A 6-point formula is used for the purpose. The routines TWOFOLD computes the folding over the densities, as used in eq. (71). Routines RHOPP and RHONP generate the liquid drop densities, and the routine PHNUC computes the eikonal integral appearing in eq. (70).

Repeated factors for the nuclear and for the Coulomb potentials are calculated in the main program and stored in the main program with the arrays PSITOT and PSINUC. These arrays are carried over in a common block to the routine VINT which computes the function  $Q_{N\lambda\mu}^{(kj)}(\xi_{kj}, \tau) + Q_{C\pi\lambda\mu}(\xi_{kj}, \tau)$ , used in eq. (69).

The optical potentials are read in routine OMP\_READ, or calculated in routines OMP\_WS (Woods-Saxon), OMP\_DEN ( $t\text{-}\rho\rho$ ) and OMP\_M3Y (M3Y). Routine TM3Y sets the M3Y interaction. DEFORM calculates the effective potentials in the Bohr-Mottelson model. SIGNNE and PHNNE return the nucleon-nucleon cross sections and the parameters of the nucleon-nucleon scattering amplitude 13. PHNUCF calculates the eikonal phase in the “ $t\text{-}\rho\rho$ ” approximation with the help of the Fourier transform of the ground state densities, provided by FOURIER.

The time integrals are performed by means of an adaptive Runge-Kutta method. All routines used for this purpose have been taken from the Numerical Recipes [27]. They are composed by the routines ODEINT, RKQS, RKCK, and RK4. The routine ODEINT varies the time step sizes to achieve the desired accuracy, controlled by the input parameter ACCUR. The right side of (69) is computed in the routine DCADT, used externally by the fourth-order Runge-Kutta routine RK4. RKCK is a driver to increase time steps in RK4, and RKQS is used in ODEINT for the variation of step size and accuracy control. The main program returns a warning if the summed errors for all magnetic substates is larger than  $10 \times \text{ACCUR}$ .

Elastic scattering is calculated within the routine ELAST for nucleus-nucleus, and ELASTP for proton-nucleus, collisions. Inelastic scattering is calculated within the main

program, and  $\gamma$ -ray angular distributions are calculated in the routine GAMDIS.

The routine THREEJ computes Wigner-3J coefficients (and Clebsh-Gordan coefficients), RACAH the 6j-symbols, or Racah coefficients, YLM is used to compute the spherical harmonics, LEGENGC the Legendre polynomials, and BESSJ0 (BESSJ1) the Bessel function  $J_0 (J_1)$ .

The routines SPLINE and SPLINT perform a spline interpolation of the excitation amplitudes, before they are used for integration by means of the routines QTRAP and QSIMP, from Numerical Recipes [27].

## XII. TEST INPUT AND THINGS TO DO

A test input is shown below. It corresponds to the excitation of giant resonance states in Pb by means of the reaction  $^{17}\text{O}$  (84 MeV/nucleon) +  $^{208}\text{Pb}$ . Assuming that an isolated state is excited, and that it exhausts fully the sum rules, one gets ( $B(E\lambda) \equiv B(E\lambda, E_x)$ )

$$B(E1) = \frac{3}{4\pi} \frac{\hbar^2}{2m_N} \frac{NZ}{AE_x} e^2, \quad (101)$$

and

$$B(E2) = \frac{\hbar^2}{m_N} \frac{3R^2}{4\pi E_x} e^2 \times \begin{cases} Z^2/A, & \text{for isoscalar excitations;} \\ NZ/A, & \text{for isovector excitations;} \end{cases} \quad (102)$$

From these values, the reduced matrix elements can be calculated from the definition in eq. 64.

**Example 1** - The input list below calculates the excitation cross sections for the isovector giant dipole (IVGDR) and isoscalar giant quadrupole (ISGQR) resonances in Pb, for the above mentioned reaction. The user should first run this sample case and verify that the output numbers check those in ref. [26]. In particular, compare the results for elastic scattering with the upper figure 2 of ref. [26]. Also compare the inelastic excitation of the IVGDR with the upper figure 3 of ref. [26]. Following this it might be instructive to change the input of energies, spins, and excitation strengths for low lying states, giant resonances, etc.

**Example 2** - Table III gives the results of an experiment on Coulomb excitation of S and Ar isotopes [28]. Choose the minimum impact parameter, BMIN, so that it reproduces the maximum scattering angle ( $\theta_{\max} = 4.1^\circ$ ) in the experiment (use the formula  $b = a_0 \cot(\theta/2)$  and read the last paragraph of section II). Using the  $B(E2)$  values in the table reproduce the cross section values (careful with the units!).

Secondadry beam	$^{38}\text{S}$	$^{40}\text{S}$	$^{42}\text{S}$	$^{44}\text{Ar}$	$^{46}\text{Ar}$
$E_{\text{lab}}$ [MeV/nucleon]	39.2	39.5	40.6	33.5	35.2
Energy of the first excited state [MeV]	1.286(19)	0.891(13)	0.890(15)	1.144(17)	1.554(26)
$\sigma(E2; 0_{g.s.}^+ \rightarrow 2_1^+; \theta_{\text{lab}} \geq 4.1^\circ)$ [mb]	59(7)	94(9)	128(19)	81(9)	53(10)
$B(E2; 0_{g.s.}^+ \rightarrow 2_1^+)$ [ $e^2 \text{ fm}^4$ ]	235(30)	334(36)	397(63)	345(41)	196(39)

Table III. Experimental results on Coulomb excitation of S and Ar projectiles impinging on a  $^{197}\text{Au}$  target [28].

**Example 3** - Compare the results of this code with those from the ECIS code [29]. But notice that the ECIS code has relativistic corrections in kinematic variables only. The relativistic dynamics in the Coulomb and nuclear interaction are not accounted for. Thus, one should expect disagreements for high energy collisions ( $E_{\text{lab}} \geq 100$  MeV/nucleon).

### XIII. OUTPUT

The output of DWEIKO are in the files

1. DWEIKO.OUT: Probabilities and cross sections;
2. DWEIKO\_OMP.OUT: Optical model potential;
3. DWEIKO\_ELAS.OUT: Elastic scattering cross section;
4. DWEIKO\_INEL.OUT: Inelastic scattering cross section;
5. DWEIKO\_STAT.OUT: Statistical tensors;
6. DWEIKO\_GAM.OUT: Angular distributions of gamma-rays.
